

Week 3 - Activity 4: design a database for your college

Design a database for YB college:

Project scope (short paragraph)

1. Write a story that defines the purpose and scope of the database. Describe the main entities (e.g., students, lecturers, etc).

Entities and EER diagram

2. List all entities with brief descriptions of their roles and attributes (e.g., Student, Course, Class, Lecturer, etc).

Table design

3. State how many tables are required after mapping the EER to a relational schema.

Yoobee College Database Introduction: To persist and manage all the college related information into a database for daily purposes we need a database which should hold every value and information of the college from top to bottom. For e.g. College is our main entity or domain and in which all the other entities are related to. So, at first we need the college database like **yb_college_db** and under this we can create as many tables as we need as related to the daily activities functioning by the college.

Now, we have **yb_college_db** which is our main domain, and when a student comes into college for a study their information can be stored into the **students** table, their programs can be listed into **programs** or **courses** tables, and college need to hire some lecturers and store their info into **lecturers** table, students can enroll into course taught by particular lecturer and data stored into **student_lecturer_info_tbl**, every student need to give exams or give assignment so their result stored into **results_tbl**. College is basically an organization so we need to hire many employees for **admin**, **library**, **finance** etc, so **employees_tbl** is needed to store their data. This is a basic example of database design and many tables can be created into our college database based on our requirements.

Entities: Programs, Subjects, Students, Library, Employees, Salary, Library, Books and Results.
